

MULTI-LAYER CONNECTOR

BACKGROUND OF THE INVENTION

(a) Field of the Invention

5 The invention relates to a multi-layer connector, and more particularly, to a multi-layer connector for transmitting computer video and audio data and comprising a plastic housing, terminals and a metal housing. Wherein, the plastic housing is consisted of a plastic body and a terminal support.

10 (b) Description of the Prior Art

Referring to FIG. 1 showing a prior signal connector installed to a computer equipment and for inputting and outputting analog audio data, because current computer equipments are generally provided with five-track functions including signal data input, microphone signal input, 15 front speaker output, rear speaker output, and center and bass speaker output, a quantity of signal connectors required is also increased. The signal connectors are mostly arranged in stacks or arranged side by side. However, when the aforesaid signal connectors are simultaneously installed at a same circuit board, a large area is inevitably occupied as a 20 shortcoming. Furthermore, it is necessary that parts of the signal

connectors be individually manufactured, and duplications are also resulted to lead to wastage. Supposed the connectors are piled and covered with metal housings, and altogether adhered to pins of a circuit board, a huge amount of housings having different shapes are needed, meaning that different molds need to be provided in advance as well. Consequently, time is wasted and production costs are elevated without conforming to market practicability and economical concerns. It is crucial that the aforesaid structure be advanced.

SUMMARY OF THE INVENTION

10 An object of the invention is to provide a multi-layer connector for overcoming the aforesaid shortcomings while also offering facilitated assembly and economized part and manufacturing costs.

To accomplish the above object, a multi-layer connector according to the invention comprises a plastic housing, terminals and a metal housing.

15 The plastic housing is consisted of a plastic body and a terminal support. A front side of the plastic body is excavated with five analog signal connecting openings having identical dimensions. The analog signal connecting openings are for accommodating signal connecting nuts therein. A rear side of the plastic body is provided with sliding channels
20 for placing and positioning terminal front ends. An upper portion of the

plastic body is disposed with a fastening mechanism for joining with the terminal support. An interior of the terminal support is divided into various compartments for accommodating various terminal main bodies.

The terminal support is excavated with terminal openings at a lower
5 portion thereof, and is provided with a fastening mechanism at an upper rear portion thereof for coordinating with the fastening mechanism of the plastic body. The terminal support also has positioning pins at a lower portion thereof for positioning the entire assembled structure to a circuit board.

10 According to the aforesaid descriptions, to assemble the structure, the terminal main bodies are inserted into the terminal support, and the terminal front ends are inserted into the sliding channels of the plastic body. The signal nuts having different colors but identical dimensions are placed in the signal connecting openings at the front end of the
15 plastic body, so as to substantially reduce mold and material costs. When the positioning pins at the lower portion of the plastic body are placed into the positioning openings at the lower portion of the terminal support, the fastening mechanisms of the terminal support and the plastic body are wedged and fastened with each other. The entire
20 aforesaid structure is covered and fixed by the metal housing, and then

altogether stabilized to pins of the circuit board for minimizing assembly time.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows an elevational view of a prior art.

5 FIG. 2 shows an exploded view of a plastic body and a terminal support according to the invention.

FIG. 3 shows an assembled structural view of a plastic body and a terminal support according to the invention.

FIG. 4 shows an elevational view according to the invention.

10 FIG. 5 shows an elevational view of a metal housing according to the invention.

FIG. 6 shows a schematic view according to the invention in use.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

To better understand the structures, devices and characteristic of the invention, detailed descriptions of a preferred embodiment shall be given with the accompanying drawings below.

Referring to FIGS. 2, 3 and 4, a multi-layer connector 1 according to the invention comprises a plastic housing 10, terminals 20 and a metal housing 30. The plastic housing 10 is consisted of a plastic body 11 and a terminal support 12. Wherein, a front side of the plastic body 11

20

is disposed with five analog signal connecting openings 11a having identical dimensions. The analog signal connecting openings 11a have dimensions corresponding to those of signal connecting nuts 13, so as to accommodate the signal connecting nuts 13 therein. Each of the signal connecting nuts 13 is a hollow hat-shaped body, and has a skirt portion 13a at a periphery thereof and a round hole 13b at a center thereof for inserting signal terminals. A rear side of the plastic body 11 is provided with sliding channels 11 for placing and positioning terminal front ends 21. An upper portion of the plastic body 11 is disposed with a fastening mechanism 11c for joining with the terminal support 12. An interior of the terminal support 12 is divided into various compartments 12a for accommodating various terminal main bodies 22. The terminal support 12 is excavated with terminal openings 12b at a lower portion thereof, and is provided with a fastening mechanism 12c at an upper rear portion thereof for coordinating with the fastening mechanism 11c of the plastic body 11. A fastening mechanism 11c of the plastic body 11 is a clamp-shaped structure. A fastening mechanism 12c of the terminal support 12 has a shape corresponding to that of a front end of the fastening mechanism 11c, and appears as a shape having a protruding edge. The fastening mechanism 12c is inserted into a gap at a front

end via a lower portion of the fastening mechanism 11c of the plastic body 11. To assemble the invention, the terminal main bodies 22 are inserted into the terminal support 12, and the terminal front ends 21 are placed into the sliding channels of the plastic body 11. Positioning pins 11d at a lower portion of the plastic body 11 are placed into positioning holes 12d at a lower portion of the terminal support 12, and the fastening mechanisms 11c and 12c of the terminal support 12 and the plastic body 11 are wedged and fastened with each other. The entire aforesaid structure is covered using the metal housing 30 and then fastened.

Referring to FIG. 5, the metal housing 30 is formed by bending and stamping a thin metal plate. A front panel 31 of the metal housing 30 is provided with five openings 31a having shapes and dimensions corresponding to the signals connecting nuts 13 and a folded line 31b at an upper portion thereof for connecting with an upper panel 32, bent at two sides thereof for forming a U shape, and reserved with recesses 31c at edges thereof. The front panel 31 further has a bending plate 31d and a fixing plate 31e at two lower edges thereof, respectively. Wherein, the bending plates 31d are for clamping and fixing the plastic housing 10, and the fixing plates 31e are for stabilizing the entire connector 1 at a circuit board 2. The upper panel 32 is provided with

cover plates 32a bent in a downward direction for corresponding with the recesses 31c at the edges of the front panel 31, and folded with a folding line 32b at an appropriate position thereof so as to fold the upper panel 32 into an L shape. The upper panel 32 further has folding plates 32c
5 at upper edges thereof for clamping and fixing the plastic housing 10.
FIG. 6 shows an embodiment of the entire connector 1 being disposed at the circuit board 2.

Conclusive from the above, the multi-layer connector according to the invention utilizes nuts having identical shapes and dimensions, and an
10 assembly of a plastic housing and a terminal support to decrease mold expenses for manufacturing, with the common parts further economizing material costs. It is of course to be understood that the embodiment described herein is merely illustrative of the principles of the invention and that a wide variety of modifications thereto may be effected by
15 persons skilled in the art without departing from the spirit and scope of the invention as set forth in the following claims.
